

(b), (c) composed from the B1 clock sweep: at each deadline, the best two-domain split against the best single clock, both scored on the same clock set under the same deadline rule. Latencies at or below the single-clock energy optimum (4.63 ms); what that restriction costs the two-domain side is measured, not assumed, and reported in data/two_domain_summary.csv.

(b) thins the MEASURED grid, so nothing in it is interpolated. Each faint line is one of the 18 anchors the thinning can start from. The exponent's uncertainty combines that anchor spread with an exhaustive bootstrap over the 6 passes, which is the larger; across all 462 distinct resamples and all 18 anchors it never exceeded 0.85.

Two domains win 41 of the 42 deadlines and tie at exactly one: the fastest, where no latency slack is left to convert into energy.
