

(a) a sawtooth, peaking just above each exact wave

(b) it is a shallow-layer effect

Both arms meet the SAME deadline, the one the split achieves. Energy is $\sum_d [n_d \kappa(f_d) + s_d P_{\text{leak}}(f_d) T]$ with κ and P_{leak} measured

(kappa_sweep.csv, idle_power.csv) and clocks on the A100's real 15 MHz grid -- a coarser grid invents gains that are pure quantisation. Search: every SM split, every clock pair, five tile assignments. The opportunity is scheduling granularity; the flat κ below the knee is only what makes the big domain's lower clock free.
